## Real-Time Systems

### Classifications

What happens upon failure to meet deadlines:

- **Soft:** performance is degraded but not destroyed
- **Firm:** a few times will simply degrade performance, but after may lead to system failure
- **Hard:** complete and catastrophic system failure
  - **Safety Critical:** may cause injury / death (a type of hard)

**Forward difference method:** derivatives using  $f'(x) = \frac{f(x+h) - f(x)}{h}$

**Backwards Difference method:** derivatives using  $f'(x) = \frac{f(x) - f(x-h)}{h}$

**Controller** [C(s)]:

**Input** [E(s)]:

**Output** [U(s)]:

$$U(s) = C(s)E(s)$$

## Task optimization

**Task** [T]:  $T_i = (p_i, r_i, e_i, d_i)$

**Period** [p]: time between tasks are repeatedly released

**Release time** [r]: time it takes to release task

**Execution time** [e]: slowest time task could take to be completed (but assume the tasks will take this long no matter what)

**Deadline** [d]: when task needs to be completed

**Number of tasks** [n]:

**Processor Utilization** [U]: used as a priority level  $U = \sum_{i=1}^n \frac{e_i}{p_i}$

If  $U > 1$ , nothing is feasible

If  $r_i = 0$  and  $p_i = d_i$ , then write  $T_i = (p_i, e_i)$

## Types of Scheduling

### Static

**Static Scheduling:**

- task's priority is assigned before execution and does not change
- If a task misses its deadline, you mess up all the deadlines after it like an airport at Christmas

### FIFO

**First In First Out (FIFO):**

- Could cause problems for tasks whose execution time is significantly shorter than the rest when there are deadlines
  - E.g.  $T_1 = (100, 3)$ ;  $T_2 = (2, 1)$
- A.K.A. **First Come, First Served (FCFS)**

**Schedule:** the order in which tasks will be executed

**Hyperperiod** [H]: the entire length of a cycle, least common multiple

**Harmonic:** every task period evenly divides every longer period

**Frame Size** [f]:

- The best way for computers to segment the schedule in a way that it verify that the appropriate tasks have been executed
- Process: try each see which is the largest frame size the follows the below constraints from 1 to  $e_{\max}$ .

- Constraints:
  1.  $f \geq \max_{1 \leq i \leq n} (e_i)$
  2.  $H \% f = 0$
  3.  $2f - \gcd(p_i, f) \leq d_i$

**Least Compute Time (LCT):** tasks with smallest execution times executed first

- Think *greedy*
- Works poorly; worse than RR

**Rate Monotonic (RM):** shorter period, higher priority

- Think: tasks requiring frequent attention should have higher priority
- If harmonic, feasible as long as  $U \leq 1$
- If non-harmonic, guaranteed feasible if  $U \leq n \left( 2^{\frac{1}{n}} - 1 \right)$ 
  - If the equation fails, it still might be, so draw the whole thing to be safe.

## Dynamic

**Pre-empting:** splitting a task up into multiple mini tasks. Also, if a task misses its deadline, halt the task at the deadline

The only two optimal dynamic priorities are:

- **Earliest Deadline First (EDF):**
  - more flexible, better U
  - If deadlines < periods, still optimal, but determining feasibility is NP-hard
  - Always feasible if  $U \leq 1$
- **Least Slack Theorem (LST):** not as popular as EDF

## Multiprocessor

Once you have multiple processors, neither EDF nor RM are guaranteed to work.

Look into first-fit algorithms

## Task Interactions

**Suspended:** active choice, of access prevention until algorithm allows it to

**Blocked:** as a result of waiting for a resource to be free

How to do the timing diagrams with locks:

- $S_1 = \text{lock}(S_1)$
- $S_1^{\wedge} = \text{unlock}(S_1)$

**One-shot Tasks:** non-periodic tasks

**Critical Section:** when a task tries to acquire an already locked by another task resource

**Priority Inversion:** a method of avoiding deadlock by telling high priority tasks to share their resources with the lower priority tasks even when it's not their turn

- Allocate time, where  $T_1$  has access to shared resource, so the time not allocated can be pre-empted
- Connect the pre-empted by  $T_1$  when  $T_1$  wants to access the resource
- Protect the resource with a semaphore
- You can make it so that tasks can use the resource even after they release the semaphore, but you risk overwriting in that time

#### Priority Inheritance Protocol (PIP):

- Temporarily raise the priority of a task only if and when it actually blocks a higher priority task; on leaving the critical section, the task priority reverts to its original value
- Issues:
  - If only one shared resource, there's only one possible schedule
  - If more than one resource blocking:
    - Blocking time may be excessively long
    - Deadlock may occur
  - If accessing multiple resources, you can only use them in the same order

#### Priority Ceiling Protocol (PCP):

- Which tasks require which resources?
- Doesn't give a shit about when they were released.
- **Priority Ceiling (PC):** maximum priority that tasks will be given
  - For a current task, the PC doesn't matter
- "The state of the art when resolving resource-contention issues"
- "Deadlock free for an arbitrary number of tasks with an arbitrary number of resources acted upon in an arbitrary way."
- Main points:
  - No locked resources, so free access
  - If resource is locked by other tasks,  $S_2$  needs to have priority of  $T_2$  higher than the PC ( $S_2$ ).  $S_1$  is (suspended)
  - Priority higher than PC( $S_2$ )
  - If any task needs priority higher than the priority ceiling, it's suspended
- When entering critical sections, check if any other tasks have resources

## Sporadic Server

**Execution Budget** [ $e_s$ ]: periodic tasks aren't flexible...

**Execution time** [ $e_i$ ]: ...sporadic tasks are

**Deadline** [ $d_i$ ]: absolute deadline

**Release Time** [ $r_i$ ]:

**Set of Sporadic Tasks** [ $\theta$ ]:

**Sporadic Task** [ $S_i$ ]:

- Non-periodic task
- ( $r_i$ ,  $e_i$ ,  $d_i$ )
- Typically interrupt-driven

**Rules** [ $\rho$ ]: set of rules regulating a sporadic server

**Sporadic Server**  $[\Phi_s]: (p_s, e_s, \theta, \rho)$

**Periodic Task:**  $(p_s, e_s)$  a type of sporadic server

Assume:

- $\Phi_s$  scheduled with  $T_i$  according to RM

We don't use  $K_d$  because it looks at the derivative regardless of the size of the error function. If your error is a sine function with a small amplitude,  $K_d$  will only take the derivative into account and it will overcompensate.

**Open loop response:** plant with no control

**Ziegler-Nichols Tuning Rule:** a PID tuning rule

Look at the *open loop response*. It could have a longer rise time / overshoot than preferred.

1. Tangent to curve on upslope

High sample rate  $\rightarrow$  lots of high frequency noise

**Effective Utilization**  $[\delta]$ :

$$U = U_{\text{periodic}} + \delta U_{\text{sporadic}}$$

## Clocks

**Computer Clock**  $[C]$ :

Attributes:

- Correctness
- Bounded Drift
- Monotonicity
- Chronoscopia

**Drift**  $[\rho]$ : rate of change of the clock value away from a perfect clock (each second)

There's usually a reason why a clock drifts

$$\left| \frac{dC(t)}{dt} - 1 \right| \leq \rho$$

(EPS):

**Monotonicity:** Clock will always have a consistent spacing and will only move in one order (forward / backwards)

SSL certs will fail signature if your clock is wrong as to ensure this

**Chronoscopia**  $[\gamma]$ : changing drift

second derivative of stuff  $\left| \frac{d^2 C(t)}{dt^2} \right| \leq \gamma$

**Error bound**  $[\varepsilon]$ :

**Acceptance Test:**  $\omega(S_k, t) = \left\lfloor \frac{d_k - t}{p_s} \right\rfloor e_s - e_k - \sum_{S_i \in \theta: d_i < d_k} e_i - \xi_i$

## PID Control

**Plant**  $[G(s)]$ : a transfer function, e.g.  $\frac{1}{s^2 + 10s + 20}$

Remember this from 3DX4? Most of the stuff is still there, so refer to that.  
Each of the K's represent a different error or gain

4 types of controllers  $[P(s)]$ :

- **Proportional Controller (P),(PC):**  $\frac{K_p}{s^2 + 10s + (20 + K_p)}$
- **Proportional Integral (PI):**  $\frac{K_p s + K_i}{s^3 + 10s^2 + (20 + K_p s + K_i)}$
- **Proportional Derivative (PD):**  $\frac{K_d s + K_p}{s^2 + (10 + K_d)s + (20 + K_p)}$
- **Proportional Integral Derivative (PID):**  $\frac{K_d s^2 + K_p s + K_i}{s^3 + (10 + K_d)s^2 + (20 + K_p)s + K_i}$

$$u(t) = K_p e(t) + K_d \dot{e}(t) + K_i \int_0^t e(v) dv$$

## Designing a PID Controller

1. Obtain an open-loop response and determine what needs to be improved
2. Add  $K_p$  to improve the rise time
3. Add  $K_d$  to improve the overshoot
4. Add  $K_i$  to eliminate the steady-state error
5. Adjust each of  $K_p$ ,  $K_d$ , and  $K_i$  until you obtain a desired overall response. You can always refer to the table below to find out which controller controls what characteristics.

| RESPONSE | RISE TIME    | OVERSHOOT | SETTLING TIME | S-S ERROR |
|----------|--------------|-----------|---------------|-----------|
| $K_p$    | Decrease     | Increase  | Small Change  | Decrease  |
| $K_d$    | Small Change | Decrease  | Decrease      | No Change |
| $K_i$    | Decrease     | Increase  | Increase      | Eliminate |

**Ziegler-Nichols Tuning Rule:** for a plant with neither integrators nor dominant complex-conjugate pairs

**Noise frequency**  $[\omega_n]$ :

**Noise amplitude**  $[a_n]$ :

Jitter

**Jitter:** a delay
